At the July 16, 2015 meeting of the Scientific Guidance Panel (SGP), the Panel recommended including the class “ortho-phthalates” as designated chemicals for Biomonitoring California. ortho-Phthalates are esters of 1,2-benzenedicarboxylic acid, with the general structure shown above.

The class ortho-phthalates is now under consideration by the SGP as potential priority chemicals. The criteria for recommending priority chemicals as specified in the enabling legislation (SB 1379\(^2\)) are:

- The degree of potential exposure to the public or specific subgroups, including, but not limited to, occupational.
- The likelihood of a chemical being a carcinogen or toxicant based on peer-reviewed health data, the chemical structure, or the toxicology of chemically related compounds.
- The limits of laboratory detection for the chemical, including the ability to detect the chemical at low enough levels that could be expected in the general population.
- Other criteria that the panel may agree to.

The tables on the following pages summarize some information relevant to the criteria for priority chemicals. For more detailed information on ortho-phthalates, including a

1 California Environmental Contaminant Biomonitoting Program (also known as Biomonitoring California), codified at Health and Safety Code section 105440 et seq.
description of the toxicity of this class of chemicals, refer to OEHHA (2015) and the additional references listed at the end of this document.

Table 1 shows those ortho-phthalates that currently are on the list of priority chemicals. The Table specifies the metabolites currently measured in urine by the Environmental Health Laboratory (EHL)\(^3\), and notes two additional metabolites planned for inclusion in an expanded analytical method. Biomonitoring California results for ortho-phthalates available so far can be accessed here: http://biomonitoring.ca.gov/results/chemical/284.

Table 2 shows examples of additional ortho-phthalates that would be included as priority chemicals if the Panel recommends the entire class be listed. The Table notes selected metabolites that have been detected in human urine and detections of the parent ortho-phthalates in dust. For more information on these ortho-phthalates, see OEHHA (2015).

Californians are widely exposed to ortho-phthalates and ongoing market shifts are expected to change exposure patterns. A recommendation to add this class to the priority list would emphasize the importance of tracking exposures to known and emerging ortho-phthalates in California residents over time.

\(^a\) Results for these phthalate metabolites were no longer reported by the Centers for Disease Control and Prevention (CDC) after the 2009-2010 cycle of the National Health and Nutrition Examination Survey (NHANES) because their concentrations were largely undetectable in previous survey periods (CDC, 2015).

\(^b\) Not currently included in the method and not currently planned for inclusion.

</table>

\(^a\) These are example ortho-phthalates. If the SGP recommends inclusion of the class as priority chemicals, the Program would determine which ortho-phthalates to focus on and the appropriate target metabolites for measurement.

\(^b\) No studies located.

\(^c\) Diallyl phthalate (parent compound) has been detected in breast milk.
