Abstract
Background Prior U.S. studies have reported higher per- and polyfluoroalkyl substances (PFASs) levels among Asian/Pacific Islanders (API) than other race/ethnicity groups. High seafood consumption may disproportionately expose API communities to adverse health effects from PFAS-contaminated seafood. We estimated associations between seafood consumption and serum PFAS levels among Chinese and Vietnamese American adults in the San Francisco Bay Area, California.
Methods From 2016 to 2017, Biomonitoring California collaborated with community partners to recruit 195 participants. Participants completed an exposure questionnaire and provided blood samples for analysis of PFASs and mercury. We pooled associations between seafood consumption and six PFASs using multivariable linear regressions adjusted for demographic covariates and immigration history using a two-stage approach.
Results PFOS, PFUnDA, PFDA, and PFNA increased 6–10% per five meals of any seafood over the past 30 days. Consuming fish more than three times per week over the past 30 days was associated with higher PFOS (38%) and PFUnDA (42%) compared to consumption below USDA guidelines of at least two meals of fish per week. Caught fish consumed three or more times per week over the past year was associated with 66–125% higher levels of PFOS, PFUnDA, PFDA, and PFNA, compared to consumption less than once per month. Consumption of non-fillet fish parts was associated with 34–124% higher PFOS, PFUnDA, PFDA, PFNA, PFHxS, and PFOA levels compared to no consumption.
Conclusions These findings suggest a significant route of PFAS exposure for two populations and identify opportunities to reduce exposures through expanding testing and developing culturally appropriate advisories for seafood consumption.

Keywords Per- and polyfluoroalkyl substances (PFASs) · Fish and shellfish consumption · Seafood consumption · Asian/Pacific Islanders (API) · California

Introduction

PFASs and seafood consumption: Lessons from the ACE Project

The Asian/Pacific Islander Community Exposures (ACE) Project measured levels of chemicals in Chinese and Vietnamese adults living in the San Francisco Bay area in 2016-2017. Prior studies have reported higher levels of perfluoroalkyl and polyfluoroalkyl substances (PFASs) in blood samples of Asian/Pacific Islanders (API) compared with people from other race and ethnic groups.

What are PFASs?
 PFASs can be harmful to human health. This large group of synthetic chemicals is used in industrial processes and in consumer products to

PFAS levels for ACE participants are higher than levels seen in the US population (National Health and Nutrition Examination Survey 2015-2016).

Since fish and shellfish consumption is more common among API communities, we used questionnaire data from ACE to look at the association between seafood consumption and levels of different types of serum PFASs: PFDA, PFHxS,

Update from the Asian/Pacific Islander Community Exposures (ACE) Project

 Cập nhật từ Dự án ACE – đọc thêm bên trong hoặc quét mã QR

Overall, seafood consumption was associated with higher blood serum PFAS levels in ACE participants. ACE participants who ate fish more than 3 times per week had 38% higher levels of PFOS compared with those who ate less than 2 times per week. When looking at seafood consumption over the past 30 days, serum levels of PFOS were 42% higher in ACE participants who ate fish more than 3 times per week compared with those who ate less than 2 times per week. Participants who ate fish more than 3 times per week had 66-125% higher levels of PFOS, PFUnDA, PFDA, and PFNA compared to those who ate less than 2 times per week. Consumption of non-fillet fish parts was associated with 34-124% higher PFOS, PFUnDA, PFDA, PFNA, PFHxS, and PFOA levels compared to no consumption.

ACE participants had higher levels of PFASs than the general U.S. population

Seafood is an important part of a healthy, well-balanced diet.

Tips for reducing PFAS exposures from seafood:
 ✓ Vary the types of fish and shellfish you eat
 ✓ Limit how much you eat fish parts like skin, head, and organs
 ✓ Eat fish and shellfish from a variety of water bodies

PFASs can be harmful to our health. They can build up in fish and shellfish, which can be a concern for people who often eat seafood. Learn more about PFASs.

Frequently Asked Questions BiomSPHERE Study

What is the BiomSPHERE Study?

The Biomonitoring component of the San Joaquin Valley Pollution and Health Environmental Research (BiomSPHERE) Study was conducted by:

This study collected urine samples in 2023 from families in Fresno and Stockton to learn about air pollution exposures in their communities.

BiomSPHERE included 64 parent-child pairs from two cities in the San Joaquin Valley.	Participants provided urine samples and answered questions about activities that could affect their exposures to the chemicals being measured in this project.	We tested the urine samples ("biomonitoring") for chemicals that can show exposure to air pollution.
--	--	--

We sent your family's biomonitoring results for polycyclic aromatic hydrocarbons (PAHs) and nicotine in April 2025 and for biomarkers of response to air pollution in September 2024. Currently, we are analyzing the study data to learn more about exposures to air pollution in Fresno and Stockton. We expect to share our findings with you and the community at public meetings this fall.

Your family's biomonitoring results for volatile organic compounds (VOCs) in urine are in this packet.

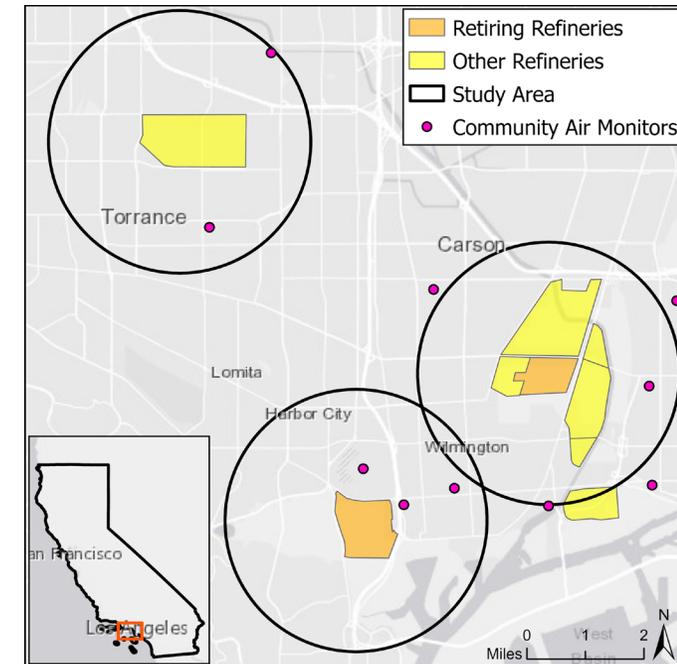

This packet provides the following information for each VOC tested:

- The level found in your and your child's urine
- Information on ways you and your child might have been exposed to the chemical
- Actions you could take to help reduce your family's exposures to the chemical

CHAIRS-LA: Community Health and Air Quality Implications of Refinery Retirements in Los Angeles Study

- Recruited 180 participants who live near oil refineries in Wilmington, Carson, and Torrance
 - Fresh Air wristbands
 - Blood pressure, lung function, and airway inflammation
- Collected urine samples from 86 participants

UCLA

Yale

CHAIRS
Community Health & Air Quality
Implications of Refinery Retirements

CHAIRS-LA: Biomonitoring Next Steps

- Urine samples are currently being analyzed for metals, specific gravity, and creatinine
- Early notification planned for participants with elevated levels of arsenic, mercury, or cadmium
- Aliquots will be stored for potential analyses for volatile organic compounds (VOCs) and polycyclic aromatic hydrocarbons (PAHs)
- Two additional samples will be collected from each participant in Fall 2026

Surveillance Studies

- CARE: California Regional Exposure Study
- MAMAS: Measuring Analytes in Maternal Archived Samples
- STEPS: Studying Trends in Exposure in Prenatal Samples

Surveillance Studies

Study	Coverage	Sample Collection	Analytes
CARE: California Regional Exposure Study	3 regions	2018 – 2020	Perfluoroalkyl and polyfluoroalkyl substances (PFASs), metals, phenols, 1-nitropyrene
MAMAS: Measuring Analytes in Maternal Archived Samples	3 regions	2012, 2015-2016	PFASs, Persistent Organic Pollutants (POPs)
STEPS: Studying Trends in Exposure in Prenatal Samples	3 counties	2015 – 2027	PFASs
Future Surveillance	TBD	2028 onward	TBD

California Regional Exposure (CARE) Study Report

Planning for Future Surveillance

- Meeting with the California Health Information Survey to discuss study parameters
- Exploring alternative sample collection methods
- Working to streamline and standardize processes
- Pilot testing Silent Spring Institute's Digital Exposure Report-Back Interface (DERBI)

Intra-Program Pilot (IPP) Study: Micro-sampling Devices

- Enrolled 40 participants
- Designed to compare two micro-sampling devices with venipuncture
 - Do micro-sampling devices collect sufficient volume?
 - Is the blood/serum collected usable by labs?
 - Are micro-samplers acceptable to participants?
 - Are there differences between samples collected by venipuncture and micro-samplers?

TAP micro-sampler

Tasso+ device

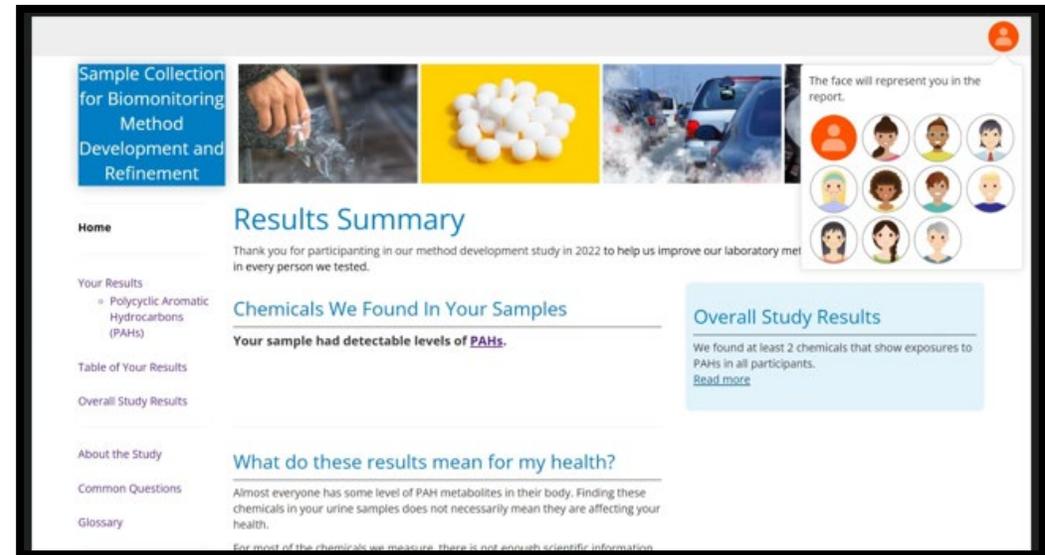

Issues with Micro-sampling Devices

- Participant experience
- Volume
- Sample quality
 - Potential for contamination
 - Coagulation of whole blood samples
- Capillary vs. venous samples

Digital Exposure Report-Back Interface (DERBI)

- Silent Spring Institute platform
- Pilot tested by OEHHA and CDPH staff

DERBI (continued)

- Impact on staff
 - Reduces workload related to results return
 - Facilitates return of multiple rounds of results
- Impact on participants
 - Enables participants to explore data in different ways
 - Allows Program to embed videos, images, and links to support participants
- Challenges – IT department/data security

Laboratory Activities

- Participating in IPPs to support lab and field method development
 - PAH metabolite results have been returned to participants
 - VOC metabolite results reported
 - Aliquots shared with external laboratory for ultrashort PFAS analysis
 - Samples collected from micro-sampling devices next in queue

Laboratory Activities: Method Development/Refinement

- IPP samples were analyzed using improved PAH method
- New method uses unique internal standards for each analyte (except 9-FLUO)
- Corrects for extraction inefficiencies, loss due to chemical reaction during solvent evaporation, matrix effects, and instrument fluctuations

Analyte	Internal Standard (Old Method)	Internal Standard (New Method)
1-NAP	2-NAP-D ₇	1-NAP- ¹³ C ₆
2-NAP		2-NAP- ¹³ C ₆
2-FLUO	2-FLUO-D ₈	2-FLUO- ¹³ C ₆
3-FLUO		3-FLUO- ¹³ C ₆
9-FLUO		2-FLUO- ¹³ C ₆
1-PHEN	3-PHEN- ¹³ C ₆	1-PHEN- ¹³ C ₄
2-PHEN		2-PHEN- ¹³ C ₆
3-PHEN		3-PHEN- ¹³ C ₆
1-PYR	1-PYR-D ₈	1-PYR- ¹³ C ₆

Laboratory Activities (continued)

- CHAIRS-LA Study: Urinary metals analyses in progress (n=187)
- CARE-2: Phenols analyses expected to begin in Spring 2026 (n=194)
- STEPS – Orange County: Data pending review for 2015-2021 samples
